Over the past 25 years, the world's population has witnessed an explosion in knowledge about infectious diseases. The global population is coming to the realization that diseases long recognized to cause substantial suffering, such as malaria, tuberculosis, schistosomiasis, and hepatitis, can be diagnosed and treated, and that transmission can be prevented using tools that are available, and which may be becoming increasingly affordable. The global population is recognizing that few infections are local: the travel of humans, other animals, insects, and food transport pathogens around the world, often with astonishing rapidity. New pathogens are appearing, either newly recognized or newly developing, such as severe acute respiratory syndrome (SARS), avian influenza,

metapneumovirus, or hepatitis C, which are causing human morbidity and mortality. Finally, there is growing fear that dangerous pathogens may be intentionally introduced into human populations by deranged individuals or terrorist organizations. The potential to use drugs or biologic agents to treat and prevent infectious diseases has increased dramatically over the past quarter century as we have learned more about the biology of many of these agents, and as we have developed techniques to discover new agents by high throughput screening programs and by sophisticated drug design and synthesis.
